## Introduction

- Annual nitrate load: 
$$L = \sum_{k=1}^N C_k Q_k$$

Where  $C_k$  and  $Q_k$  are flow and concentration value in time  $k$ .

- For financial and technical reasons, nutrient loads in rivers are often calculated from **infrequent discrete water samples**.
  - Ex: Weekly, bi-weekly, or monthly samples
- The results are just **partial** information on the concentration variations.
- Therefore, this induces **uncertainty** on the loads calculations.

## Sources of Uncertainties

In practice, when we are measuring nutrients loads, there are sources of uncertainties:

1. Uncertainties on flow rates and cumulated flow.
2. Uncertainties due to the sampling location in the water column.
3. Uncertainties due to sample degradation between sampling and analysis.
4. Uncertainties of laboratory analyses.
5. Uncertainties associated with infrequent sampling

3/22/2011 WRRRI

## Uncertainties associated with infrequent sampling – (1)

Question: Why we need sampling?

In a **perfect** world, we have continuous data:

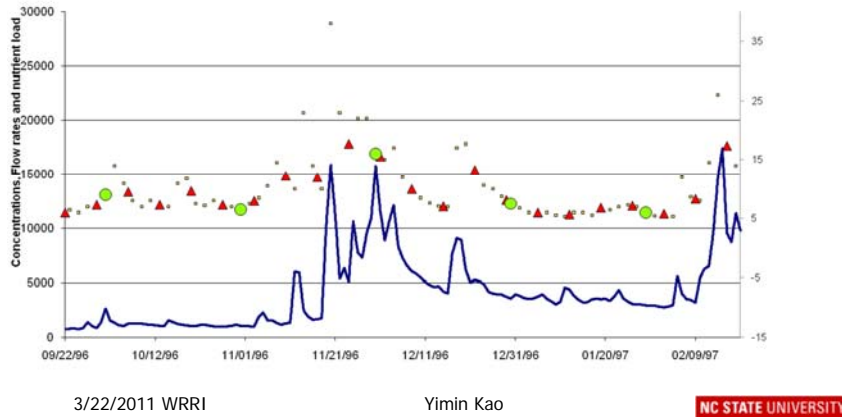

3/22/2011 WRRRI

Yimin Kao

NC STATE UNIVERSITY

## Uncertainties associated with infrequent sampling – (2)

However, in **reality**, we possible be able to have continuous data for the flow, but **not** for the concentration:

## General Objectives

- Estimate the level of **uncertainties** for the existing nutrient loads on North Carolina rivers.
- Provide **guidance** for watershed managers on their sampling strategies and frequencies according to the potential level of uncertainties.
- Provide statistical methods and models to **lower** the level of uncertainties.

3/22/2011 WRR1

Yimin Kao

NC STATE UNIVERSITY

## Methods

1. Use **reference** continuous flow and concentration data to calculate the **reference loads**.
2. We numerically **simulate** discrete sampling.
3. Calculate the loads from simulated samples using **algorithms**.
4. Calculate the **error** as relative difference between the reference loads and the simulated loads.
5. Derive the **expected level of uncertainty** for North Carolina conditions.

## Reference Data

- **Continuous** flow and nitrate concentration data from the RiverNet.
- Five stations on the Neuse River.
  - The results of one presenting today:

## Algorithms for calculating fluxes

- There are plenty of algorithms for calculating fluxes.
- We present the top two algorithms that have the best estimation:
  - « Averaging method » (M5)
  - « Linear interpolation method »

3/22/2011 WRRl

Yimin Kao

NC STATE UNIVERSITY

## Averaging Method

Formula:

$$\hat{L} = K \overline{Q} \frac{\sum_{i=1}^n C_i Q_i}{\sum_{i=1}^n Q_i}$$

3/22/2011 WRRl

Yimin Kao

NC STATE UNIVERSITY

## Linear Interpolation method

Formula:

$$\hat{L} = K \sum_{k=1}^N C_k^{\text{int}} Q_k$$

## Error Distribution

- In our study, we have the reference loads, so we can **calculate the error** that made by the estimation.
- There are **infinite number** of possible errors for “each” sampling frequency.
- Therefore, we can look at the **distribution** of the errors.

NC STATE UNIVERSITY

## Relationship between Sampling strategy and Error distribution

- Main Idea: "More often we sampled, less errors we got."
- Data from Neuse River Basin watershed.

## Extrapolating results

- In this stage, we have uncertainty obtained from reference watersheds, but we are interested in uncertainty from **other watersheds**.
- Can we relate level of uncertainty with some types of **watershed characteristics**? Yes!! It has been done already in previous researches!!
- Then use this relationship to predict the level of uncertainty for **non-reference watersheds**.

## Reactivity Indicator-(1)

- A characteristic to describe the behavior of the flow in a period of time.
- $V_{w\%} \rightarrow$  Percentage of the "sorted cumulative flow" under  $w\%$  of "cumulative time".
- Sorted cumulative flow:

NC STATE UNIVERSITY

## Reactivity Indicator-(2)

- What does Reactivity Indicator tells us?

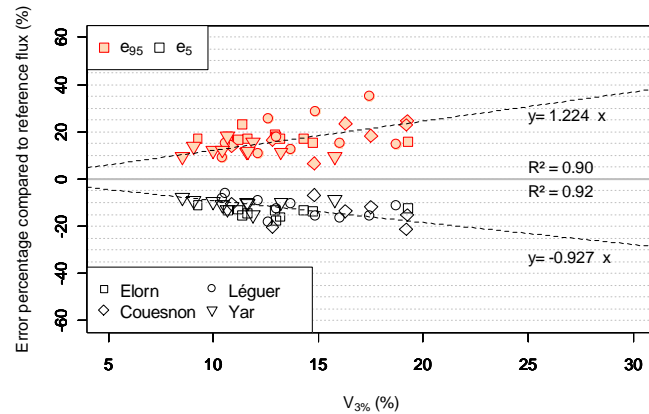

3/22/2011 WRR1

Yimin Kao

NC STATE UNIVERSITY

## Relationship between Error distribution and Reactivity Indicator

Note: This is for one specific sampling frequency.

NC STATE UNIVERSITY

## Future Works

- More watersheds data to complete the sampling frequency chart for North Carolina.
- Improve the algorithms of calculating fluxes.
  - Introduce new covariates, such as “Turbidity”, “SpCond”, and “Water Temperature”, in the algorithm.
  - Introduce **time correlations** in the models.
  - Consider **Spatial correlation** between different watersheds.
